USER MANUAL

Contents

YOU MUST READ THIS MANUAL BEFORE DOING ANYTHING WITH YOUR SQUIRREL EQUIPMENT

About this Manual

This manual does not provide instructional information, and is not a substitute for professional training, instruction, or experience. Before using this parachute, it is critical that you receive training and instruction for its use by a certified / rated instructor who is familiar with the characteristics of a 7-cell low-porosity parachute system. It is mandatory that you receive professional training and instruction on the deployment, flight, landing, packing, assembly, and maintenance of this parachute. This manual is only a general guide and does not contain any instructional information.

This manual may be updated, revised, or changed by Squirrel LLC without notice, at any time. Contact Squirrel LLC to be sure that you have the most up to date version of this manual. It is imperative that you read this manual in its entirety, and understand it fully. If you do not understand any part of this manual, or feel that any part is unclear in any way, please notify Squirrel LLC in writing and do not use any equipment that this manual refers to until you are certain that you fully understand the most up-to-date information pertaining to your equipment.

Your Squirrel EPICENE PRO comes with NO WARRANTY.

Parachuting, skydiving, and wingsuit flying are extremely dangerous activities. This parachute is sold with all faults, as is, and with no guarantee or warranty of fitness for any purpose. Squirrel LLC, its members, owners, associates, and dealers, disclaim any and all liability in tort for damages of any kind, caused by negligence on the part of Squirrel LLC or otherwise. By using this parachute system or allowing it to be used by others, the user waives any liability of the manufacturer for personal injuries or other damages resulting from its use.

⚠ WARNING ⚠

ALL FORMS OF SKYDIVING, PARACHUTING, AND WINGSUIT FLYING ARE INHERENTLY HAZARDOUS ACTIVITIES AND REQUIRE THE DELIBERATE AND CONSCIOUS CONTROL OF YOUR PHYSICAL BODY THROUGH THE PROPER USE OF THIS PRODUCT IN RELATION TO EVER-CHANGING VARIABLES AND DANGERS. TRAINING, PROFICIENCY, SKILL, GOOD JUDGMENT, AND BEING CONTINUALLY ALERT TO CHANGING CONDITIONS, INCLUDING WEATHER, VISIBILITY, SURFACE CONDITIONS, ATMOSPHERIC CONDITIONS INCLUDING DENSITY ALTITUDE, AND OBSTACLES, ARE REQUIRED TO LOWER THE RISK OF SERIOUS INJURY OR DEATH. DO NOT USE THIS PRODUCT WITHOUT INSPECTING IT AND ALL OF ITS COMPONENTS BEFORE EACH AND EVERY USE.

!!! Even when properly used, this product may malfunction or fail to operate as expected. You risk death or serious injury each time that you use this parachute system !!!

The EPICENE PRO is a 7-cell low-bulk high performance parachute system designed for experienced parachutists ONLY. Refer to this manual for experience requirements. You must have at least 200 skydives and a thorough understanding of the performance differences between this canopy and other more common parachute systems before using this parachute. Do not use this parachute unless you meet the minimum experience requirements outlined in this user manual, and have received training and instruction on the proper use of a 7-cell canopy constructed from low-bulk / 0-3cfm materials. Packing, opening, flight, and landing characteristics may vary greatly from other parachutes you have previous experience with.

General Information & Flight Characteristics

About The EPICENE PRO

The EPICENE PRO is specifically designed to deliver consistent and reliable openings while wingsuit skydiving. We have never jumped a skydiving parachute that opens so cleanly, immediately, and comfortably, and in such a short amount of altitude. For us, this parachute has been a game-changer, and it has greatly improved our skydiving enjoyment while testing and flying the larger suits in our range - actually, all suits. When we skydive wingsuits of any size, the EPICENE PRO is now our parachute of choice.

The EPICENE PRO is based on the very same design tenets that make BASE jumping canopies reliable, but we tuned the design to deliver more glide performance, softer openings, and better handling. We have tested the EPICENE PRO with a variety of packing methods and with different deployment techniques, and its design is meant to ensure the best overall opening consistency available today.

Although the openings are faster than traditional skydive canopies, they are not uncomfortable typical deployment airspeeds.

Flight Characteristics

The EPICENE PRO is a specialist design that is meant specifically for experienced skydivers to use during wingsuit skydiving. Today's modern wingsuit pilots are flying larger and higher performance wingsuits that have the potential to create significant wake turbulence. Many modern wingsuit designs are restrictive and do not allow the freedom of movement that is available during normal skydives to deal with parachute malfunctions. For these reasons, we designed a parachute that, according to our testing and experience, is most likely to deliver consistent on-heading openings during wingsuit use.

When using the EPICENE PRO for the first time, be aware of the fact that many factors will determine the quality of your parachute openings. If you take the necessary steps to configure your equipment properly, we are confident that the EPICENE PRO will become your parachute of choice for wingsuit applications.

Glide Performance:

The EPICENE PRO's glide performance is typical of a low aspect ratio 7-cell parachute. The EPICENE PRO's ZP leading edge provides increased glide performance and flare power over canopies made entirely from 0-3 cfm (Cubic Feet / Minute) fabric, but the low aspect ratio design and low-porosity main surfaces do not yield the same glide performance as an all ZP design.

Toggle Inputs and Overall Handling:

Piloting the EPICENE PRO is straightforward and fun. It has a sporty and highly compact feel in the air, with direct control inputs and progressive brake-travel. The EPICENE PRO rolls into a turn quickly, but also returns to level flight quickly when control inputs are ceased. The control range is progressive, with building pressure towards the end of the range. Thanks to a carefully moderated spanwise sail tension, the EPICENE PRO's handling is fun and forgiving with a responsive and coordinated feel, overall.

Front Riser Input:

The EPICENE PRO has a relatively short recovery arc from front riser turns. It can be fun to land using front riser turns on approach, but is quite obviously not a high performance swooping canopy. If you are coming from a 9-cell ZP design, you may find that the EPICENE PRO has a different recovery arc. Always start with gentle high-altitude front riser inputs. Do not attempt low turns with any canopy until you have extensive experience with it.

When manipulating front risers, remember that brake/control line length may need to be lengthened to allow certain front riser control inputs. If you are influencing the trailing edge of the canopy too much during front riser inputs, you may need to slightly lengthen your control lines. Keep in mind that adjusting control line length will affect your flare and control range. There is a limit to how much front riser input the EPICENE PRO can take before the trailing edge is affected by the control line length.

Rear Riser Input:
The EPICENE PRO responds to front and rear riser input similarly to other low aspect ratio 7-cell designs. Its glide can be flattened by applying a small amount of rear risers. EPICENE PRO pilots should be aware that the rear riser range is shorter (stall is more easily achieved) compared to traditional 9-cell ZP canopies.

Landing:
When loaded appropriately according to the recommended weights, the EPICENE PRO is not a difficult parachute to land, compared to traditional 9-cell canopies at higher wing loadings. The point of the EPICENE PRO is to be able to easily reduce your main canopy wing loading without changing your container system – **so you should be jumping a size larger than you normally would**. If you are loading the EPICENE PRO at the higher end of the recommended range, advanced to expert canopy skills are recommended.

Choosing Your Canopy

Jumper Experience
Do not use your EPICENE PRO until or unless you have at least 200 skydives, and at least 50 skydives using a parachute that is at least 20% SMALLER than the size of EPICENE PRO you intend to jump (for example, if you intend to jump a 170 EPICENE PRO, you should have experience landing a 136 (or smaller) canopy, safely and comfortably, at least 50 times).

The EPICENE PRO's 7-cell design and low-bulk 0-3 cfm materials were chosen to maximize opening performance for wingsuit skydiving use. Compared to some 9-cell ZP parachute designs, the EPICENE PRO has less flare power and has a lower glide ratio. As with any low-porosity 7-cell canopy, it is critical that you have at least solid intermediate or advanced canopy skills in order to land it comfortably.

The EPICENE PRO's flare characteristics at normal density altitudes and recommended wing loading are adequate for most parachutists/skydivers of intermediate skill, even without front riser acceleration or a diving turn.

Wing Loading
Given that the EPICENE PRO is meant to be used only by experienced skydivers and wingsuit pilots, you should already have a clear understanding of the definition of wing loading and the proper method to calculate it before choosing your canopy.

However, let's review it briefly: Wing loading is calculated by dividing the total in-flight weight of the jumper by the surface area of the canopy, measured in square feet. To measure your in-flight weight, stand on a scale wearing your normal jumping clothing, your wingsuit, and your parachute system including your main canopy, and any accessories. This will typically be in the range of 30 lbs greater than your naked weight. For a jumper with an in-flight weight of 185lbs who intends to jump a 170 square foot canopy, we can estimate:

185 lbs ÷ 170 sq ft = 1.088 per square foot, or commonly written as 1.088:1

1.088 would be an acceptable wing loading for an experienced skydiver on this size of canopy.

Why the EPICENE PRO is better for wingsuiting
Today, many skydivers are jumping canopies that are generally considered to be too small (measured by wing loading), or too high aspect ratio (or too elliptical, or tapered), for use with wingsuits. Many 7-cell designs which are commonly considered to be acceptable for wingsuit use are also proving to be less than ideal, even when moderately loaded.

The EPICENE PRO is different from other available skydiving main parachutes in two important ways:

1. *Ultra low pack volume*. The low pack volume of the EPICENE PRO means that if you are currently jumping a skydiving container system which is sized for a main parachute that you are loading too highly to wingsuit with comfortably, a much larger size of EPICENE PRO will fit in your current container. For example, if you are jumping a typical cross-braced canopy in the 90 square foot range, an EPICENE PRO 130 will fit comfortably in the same container system. Reducing your wing loading is one of the first and most important factors for improving opening consistency.

2. *Low-porosity main surfaces*, ZP leading edge. It is no secret that low-porosity fabric is more stable, and yields more predictable openings. ZP fabric, in contrast, is longer-lasting and higher-performing but yields less consistent openings. For this reason, we have used ZP fabric for the leading edge of the EPICENE PRO, for aerodynamics (porosity at the leading edge is most critical for glide performance) and longevity, and ultra-light 0-3 cfm cloth for the main surfaces. This blend of materials has provided the EPICENE PRO with very low pack volume, better glide performance than an all 0-3 cfm canopy, and more consistent openings than any other main canopy we have tested.

Non-Wingsuit Use
As stated elsewhere in this manual and in the product description, the EPICENE PRO is designed specifically and primarily for experienced wingsuit pilots to use while wingsuit skydiving. If you choose to jump the EPICENE PRO without a wingsuit, always deploy at airspeeds within the operating limits of the canopy.

The ideal pilot chute size for wingsuit use is not the same for Freefly/RW/typical non-wingsuit skydives. It may be necessary to change your pilot chute for non-wingsuit jumps.

The ideal packing technique for wingsuit use is not the same as for Freefly/RW/typical non-wingsuit skydives. It may be necessary to adjust your packing technique for non-wingsuit jumps. In addition to a more appropriate pilot chute size, we recommend a more tightly rolled tail, a rolled and/or carefully prepared nose, and extra attention to slider positioning. Finally, always moderate your freefall speed to within the canopy operating limits before deployment.

Some Information About Wingsuit Parachute Openings

PLEASE NOTE: The PC selection, bridle size, packing techniques, etc, which are discussed in this manual are not only specific to the EPICENE PRO. This is information that, according to our testing and experience, applies to any canopy used for wingsuiting.

Openings, and the factors that determine opening characteristics
It is important to tailor your openings to your desired speed, consistency, and force, by controlling not only packing technique but also airspeed and body position at deployment. The EPICENE PRO's design is optimized for opening consistency; however it is up to the jumper to ensure that all factors are properly considered and controlled in order to maximize the chances of a desirable result.

Pilot Chute (PC)
When flying a wingsuit, a larger pilot chute than what is typically used for normal skydiving is recommended. We recommend a 26" to 30" ZP toroidal arc design such as the SkySnatch. Choose the size based on your typical airspeed at deployment, which will vary with wingsuit type and experience. Contact Squirrel LLC for guidance on PC size selection, if needed.

Always configure your equipment under the guidance of a qualified rigger with wingsuit knowledge and experience. Pilot chute designs and materials vary, and it is not possible to recommend one ideal pilot chute type or size for all wingsuit use. Many factors affect parachute deployments. Based on guidance from experienced wingsuit instructors, you should choose a PC that is most appropriate for your canopy size, wingsuit type, and the conditions you are jumping in.

Bridle
Bridle length is a key factor for wingsuit jumping. It is recommended to use a bridle that is long enough to extend the pilot chute beyond the worst area of wake turbulence behind you during deployment. Many skydiving bridles are considered to be too short for wingsuit use. Today, many wingsuit pilots use bridles that are in the range of 8 feet (2.4m) in length, from pin to PC.

Deployment bag
Testing has shown that stowless and semi-stowless d-bags yield better openings than traditional rubber-band-stow d-bags. Consider their use under the guidance of an experienced rigger who understands the factors around wingsuit parachute deployments. Heavy magnet-closed stowless bags are NOT recommended.

Slider Positioning
During packing, it is critical that you position your slider symmetrically and seat it properly against the slider-bumpers on your canopy. The size and aspect ratio of the EPICENE PRO's slider is designed specifically for this canopy, and it is vital that you consult with Squirrel before changing your slider.

Collapsing and resetting your slider
The EPICENE PRO's collapsible slider must be reset to the fully extended position each time you pack your parachute. Failure to do so may result in equipment damage, serious bodily injury, or death.

Controlling your Burble (wake turbulence)
Wingsuits can create large burbles, or wake turbulence, compared to what is common during normal skydives. This turbulence can have negative effects on the quality of your parachute openings. In order to increase the chances of a desirable opening, it is important to minimize your pilot chute and parachute's exposure to wake turbulence. This means that you must understand the causes of the turbulence and the remedies to reduce it.

Wingsuit wake turbulence is determined, in part, by three important factors: angle of attack, airspeed, and wingsuit surface area.

1. *Angle of Attack* – At deployment, the ideal angle of attack allows a smooth and laminar airflow across the top surface of your wingsuit, without excess airspeed. If your angle of attack is too high (meaning head-high to the relative wind), then the turbulence behind you will be increased. If your angle of attack is too low (meaning head-low to the relative wind) then your airspeed may be too high, which could degrade opening performance and increase the chances of an excessively hard opening. Deploying at the correct angle of attack and airspeed is a skill that must be learned and practiced.

2. *Airspeed* – When wingsuit flying, airspeed is largely determined by angle of attack. Airspeed can be reduced by "flaring" your wingsuit briefly before opening, and this is the recommended technique to moderate your airspeed before deployment. However, it is important that you do not deploy in the middle of a too-powerful flare at a high angle of attack as this will mean deploying into a large amount of wake turbulence. The favored technique is to flare to reduce airspeed, and then return to a more level angle of attack at a reduced airspeed to allow a more laminar flow over the top surface of your suit.

3. *Wingsuit Surface Area* – The larger your wingsuit is, the more potential it has to create wake turbulence. Larger suits are also capable of slower airspeeds. Smaller wingsuits may create less wake turbulence, but the wake can still be quite severe depending on the angle of attack and forward speed. It is important to deploy with some laminar airflow over the top surface of your suit (therefore an angle of attack that is not too high) but at an airspeed that is low enough for a comfortable opening. Inexperienced wingsuit pilots flying small wingsuits may find it challenging to achieve a balance between a lower angle of attack, and a comfortably low airspeed.

Opening Inconsistencies

Line Twists

Wingsuits add a great deal of complexity to skydiving, particularly during the deployment and canopy piloting phases. When wingsuiting, one of the most common issues during deployment is "line twists," which sometimes occur between d-bag deployment and canopy inflation. There are many factors involved, including symmetrical body position through the entire deployment sequence, correct body positioning, and proper packing techniques. Reaching for risers asymmetrically, twisting your body during deployment, flying your leg wing asymmetrically, or not flying your heading until the canopy is fully inflated will all contribute to degraded opening performance.

One of the most common moments that line twists occur is at or immediately after line stretch, prior to pack job expansion and inflation. **The common packing method of "rolling the tail" around the pack job and lines encourages line twists during a wingsuit deployment.**

During wingsuit parachute deployment, the chain of equipment is spread more horizontally than it is during a typical non-wingsuit skydive deployment. In addition to that, the wingsuit creates a large "burble" or area of wake turbulence, which degrades opening performance. These two factors must be understood and accounted for when skydiving a wingsuit.

The more horizontal nature of a parachute deployment from wingsuit flight means that the pilot chute, bridle, pack job, and canopy lines can all be stretched out to an almost 180 degree plane during deployment, and at a lower airspeed than a typical skydive opening. At this stage, the pack job is more susceptible to rotation and off-heading openings. If the tail is rolled tightly around the lines and the pack job, then the time during which the pack job is allowed to rotate at the end of the line-stretch phase is increased.

By rolling the tail together less, or not at all (SEE PACKING PHOTOS), the pack job will begin expansion sooner and have less time to rotate or turn at the end of the line-stretch phase. The less time your pack job spends being buffeted around in wingsuit wake turbulence, the less chance there is of line twists or a more serious malfunction. We recommend not rolling the tail around the lines at the trailing edge of the pack job. It is best to only lightly fold the tail together, starting at least 10" below the lines, so that airflow can enter the pack job to allow expansion and inflation. The trailing edge (tail) of the canopy should be so loosely wrapped around the lines that a "hole" approximately the width of the warning label is apparent when the packjob is set down on the ground to be reduced into the d-bag.

Stages of pack job-rotation-induced-line-twists:

1. Parachute extends to line-stretch in a more horizontal plane than a typical skydive due to the wingsuit's glide path.

2. Pack job expansion and parachute inflation is delayed by packing technique, burble (wake turbulence), or other factors.

3. Pack job rotates, caused by burble (wake turbulence), and delayed pack job expansion. Line twists are now set.

4. Pack job expands, with the line twists set. Canopy inflation occurs, with line twists set between the slider and the risers.

5. Jumper is suspended beneath the canopy with line twists set, and must now rotate his/her body under the canopy to resolve the line twists.

What happens next depends on many factors. If the jumper/pilot has induced an asymmetry in the system by giving unequal harness input, there may be a weight-shift input locked into the twists, which can cause the parachute to begin a turn. If the turn is fast enough, the parachute may begin a spiral (oftentimes incorrectly referred to as a "spin") descent.

ALL canopies are susceptible to line twists when they are subjected to wingsuit wake turbulence at line stretch. The EPICENE PRO is no exception. Therefore, please consider these points and adjust your packing technique accordingly. By not rolling the tail too tightly around the pack job you can help to encourage a faster expansion, which can also mean a faster opening. For that reason, you must understand how to control your airspeed and angle of attack during deployment. The EPICENE PRO's design and materials are optimized to provide a tolerable opening even with a faster than average canopy expansion. There is a fine line between fast openings and hard openings. When packed properly and deployed at moderate airspeeds, the EPICENE PRO's opening characteristics maximize the on-heading design we have tested, making the canopy ideally suited for wingsuiting.

The EPICENE PRO is designed to be less susceptible to rapid descending spirals (oftentimes incorrectly referred to as "spins"). Due to several design factors including aspect ratio, extensive testing has shown that the EPICENE PRO is more likely (compared to a typical 9-cell ZP canopy) to maintain level flight after opening with line twists, affording the pilot with more time to deal with the situation.

Body-twists

The most common cause of "twists" after a wingsuit opening results from a rotation of the pilot underneath an inflated or partially-inflated canopy during and immediately after opening. Instead of the packjob turning during deployment, the pilot turns under the inflated or opening parachute.

The prevention of, and cure for, "body twists", is a question of wingsuit piloting technique and must be trained for. Please refer to the LEARN pages at **www.squirrel.ws** and the KNOWLEDGE BASE pages at **www.nextlevel.ws** for more information on riser control and line twist recovery.

Hard Openings

Most factors surrounding parachute openings can be controlled or influenced by the jumper. If you are experiencing hard openings, then you need to make adjustments to one or more of the following factors:

1. *Equipment:* check pilot chute size, d-bag type, slider size.

2. *Packing technique:* check slider positioning, nose packing method, line stowage. Seek assistance and guidance from professional packers and riggers with wingsuiting experience.

3. *Airspeed:* If the EPICENE PRO slider is correctly placed and configured, and the parachute is packed properly, openings are generally very comfortable at terminal slick airspeed, or typical wingsuit airspeeds.

Packing Your EPICENE PRO

We recommend PRO (Proper Ram-air Orientation) packing your EPICENE PRO. For wingsuit deployments, it is not necessary to roll the nose or dress it in any special manner. Consistent with normal PRO packing technique bring lines to the center of the pack job with folds neat and symmetrical.

Bring the trailing edge (tail) around the pack job. For wingsuit deployments, **do not roll the tail tightly around the pack job**. One or two simple folds, well below the line group, is adequate. Please note that the trailing edge is only folded slightly at the lower (the packer's right) hand. At the line group, there is plenty of "open" tail.

Lay the pack job down on the ground as per standard PRO packing technique. Thanks to the ultra-light material, this part will be much easier than you're used to! **Remember to leave some open space where the tail wraps around the line group**. *Do not tightly wrap the tail at this section!*

Reduce the pack job volume in preparation for d-bag placement. For wingsuit deployments, remember to leave the tail section open enough to allow airflow in during extraction.

Reduce the canopy in preparation for d-bag placement.

Stow your lines properly according to the type of deployment bag you are using.

Operating Limits

The EPICENE PRO has been independently load tested, is constructed from the highest quality materials currently available, and is built to industry-standards for main parachute systems; however it is not designed to be opened at speeds far above which are typical during a properly executed freefall deployment. The recommended maximum opening speed is 100 KEAS (Knots, Equivalent Air Speed) at Sea Level.

The maximum opening speed is 120 KEAS. Always respect the maximum opening speeds and the operational limitations of your equipment. Failure to do so, by exceeding the placarded opening speeds or maximum weights may result in serious injury, equipment failure, or death.

As with any parachute system: Even when well below the maximum opening speed, equipment failure, serious injury, or death may occur as a result of improper or imperfect packing, improper or imperfect body position, or improper or imperfect gear configuration. And finally, to hammer home the point that skydiving is always dangerous, even if you do everything perfectly and properly you can still be seriously injured, or die. That is the nature of skydiving and parachuting. Always remember that each and every jump is potentially fatal, and constant vigilance is mandatory. You are the person responsible for your safety.

Care and Maintenance

When properly cared for, the EPICENE PRO will last most skydivers for many jumps. In service since 2014, the original EPICENE has served many pilots well for more than 1000 jumps. The factors that will shorten the lifespan of your canopy are primarily Moisture, Heat, UV Exposure, Hard Openings, and Improper Storage:

1. Keep your canopy dry at all times. All moisture exposure will degrade the cloth. Avoid water landings, and try to keep your canopy away from moist or wet landing areas. Never pack or store your canopy when wet or damp. If your canopy becomes wet or damp, hang dry it in the shade, NOT in direct sunlight.

2. Do not store your canopy in a hot location. Avoid leaving it in hot vehicles, for instance.

3. Do not expose your canopy to unnecessary or excessive UV/sunlight – obviously your canopy is not allergic to the sun, but we don't recommend letting it sit out in direct sunlight unnecessarily.

4. Avoid hard openings. Pack appropriately, and moderate your airspeed at deployment.

5. For periods of extended non-use, store your canopy unpacked, in a cool, dry, dark location, away from solvents, batteries, or any chemical that will damage or degrade synthetic materials. Exposure to car battery acid or even the fumes emitted from car batteries will degrade your canopy and other nylon skydiving equipment. Always discard/destroy any equipment that has had significant exposure to battery acids or harmful solvents.

6. Keep your canopy clean, and out of the dirt and dust as much as possible. Allowing any type of dirt, sediment, or debris to accumulate inside your canopy or on the exterior surfaces will degrade your canopy's lifespan. Packing a dirty canopy will cause sediment to abrade the surfaces of the materials.

A necessary part of maintaining your canopy is understanding and recording its usage. We recommend logging every jump that you make on your EPICENE PRO, and recording deployment parameters for each jump such as wingsuit, non-wingsuit, type of wingsuit, estimated airspeed, etc.

EPICENE PRO line sets are made to exacting specifications. Replacement line sets can be ordered directly from Squirrel LLC. We do not recommend purchasing line sets from your local rigger.

In addition to you inspecting the EPICENE PRO before each jump, your EPICENE PRO should be thoroughly inspected by a certificated rigger every 200 jumps or annually (whichever comes first), or whenever it is potentially exposed to conditions including but not limited to those listed above.
